**1.9 ★** In elementary trigonometry, you probably learned the law of cosines for a triangle of sides  $a$ ,  $b$ , and  $c$ , that  $c^2 = a^2 + b^2 - 2ab \cos \theta$ , where  $\theta$  is the angle between the sides  $a$  and  $b$ . Show that the law of cosines is an immediate consequence of the identity  $(\mathbf{a} + \mathbf{b})^2 = a^2 + b^2 + 2\mathbf{a} \cdot \mathbf{b}$ .

$$(\vec{a} + \vec{b})^2 = (\vec{a} + \vec{b}) \cdot (\vec{a} + \vec{b})$$

$$= \vec{a} \cdot \vec{a} + \vec{b} \cdot \vec{b} + 2\vec{a} \cdot \vec{b}$$

$$c^2 = a^2 + b^2 + 2\vec{a} \cdot \vec{b}$$

$$= a^2 + b^2 + 2|\vec{a}||\vec{b}|\cos\phi$$

$$\phi = \pi - \theta$$

$$= a^2 + b^2 + 2|\vec{a}||\vec{b}|\cos(\pi - \theta)$$

$$\rightarrow \cos(\alpha \pm \beta) = \cos\alpha \cos\beta \mp \sin\alpha \sin\beta$$

$$\alpha = \pi \quad \beta = \theta$$

$$\cos(\pi - \theta) = \underbrace{\cos\pi}_{-1} \cos\theta + \underbrace{\sin\pi}_0 \sin\theta$$

**1.24 ★** In case you haven't studied any differential equations before, I shall be introducing the necessary ideas as needed. Here is a simple exercise to get you started: Find the general solution of the first-order equation  $df/dt = f$  for an unknown function  $f(t)$ . [There are several ways to do this. One is to rewrite the equation as  $df/f = dt$  and then integrate both sides.] How many arbitrary constants does the general solution contain? [Your answer should illustrate the important general theorem that the solution to any  $n$ th-order differential equation (in a very large class of "reasonable" equations) contains  $n$  arbitrary constants.]

**1.25 ★** Answer the same questions as in Problem 1.24, but for the differential equation  $df/dt = -3f$ .
